RESEARCH

MOTIVATION

Issue:

METHODOLOGY

Generative adversarial networks: (Goodfellow et al., 2014)

• Minmax game between two players:

- Deep learning or in general machine learning algorithms require immense amount of data to achieve high performance and to generalize well. (Norvig, 2011; C. Sun et al., 2017)
- Data acquisition and annotation can be highly time consuming and prone to errors, especially in domain specific applications (Montani and Honnibal, 2017; Y. Sun et al., 2017)

Possible solution:

- Use generative modelling to produce artificial data samples that mimics properties of real data samples
 - Artificial data samples might be used for pretraining deep learning models, while the valuable real data is saved for finetuning the model.
 - Generated data samples might provide different plausible combinations of modalities, than are present in the original real data
 - E.g. color, texture, shape

Challenges:

- Generate realistic looking data
- Model high intra- and inter-class variance in the artificial data
 - And possible control of these variations through conditioning

REFERENCES

- - A discriminator, distinguishing real and fake data samples
 - A generator, producing artificial sample in an effort to cheat the discriminator.

 $\min_{G} \max_{D} V(D,G) = \mathbb{E}_{x \sim P_{data}}[\log D(x)] + \mathbb{E}_{x \sim noise}[\log(1 - D(G(z)))]$

InfoGAN: (Chen et al., 2016)

- Unsupervised condition for structuring/controlling the appearance of the generated samples.
- Try to maximize the mutual information between the an additional latent variable generator input and the generated samples
 - Formally implemented as an additional regularization term in the objective:

EXPERIMENTS & RESULTS

Setup for creating artificial MNIST colour images:

- Increasing the challenge by randomly colouring of MNIST data •
 - Changing the generator to output a RGB image, instead of grayscale
- Latent variable design
 - 3 continuous variables (random uniform in the range [-1;1])
 - 1 categorical variable (one-hot encoded, K = 10, p = 0.1)
- Able to capture the underlying categorical structure
- Able to capture dominating continuous variations in the data (color, shape, style, ect.

Improvements to be made:

- Higher resolution is needed for more details in the generated images (Karras et al., 2017; Zhang et al., 2017)
- Better objective formulation to increase training stability (Gulrajani et al., 2017; Salimans et al., 2018)

Figure 2: Categorical variations. Each figure show the representation learned for each categorical latent variable. Each is generated by interpolating along the first and second continuous variable (x-axis and y-axis respectively)

Figure 1: continuous variations. Each figure show different combinations of interpolating along two of the continuous latent variables (one along the x-axis and one along the y-axis), with the last one fixed at 0.
